An Accelerate Process for the Successive Approximations Method
In the Case of Monotonous Convergence

Abstract

We study an iterative process to accelerate the successive approximations method in a monotonous convergence framework. It consists in interrupting the sequence of the successive approximations method produced at the \(k^{th}\) iteration and substituting it by a combination of the element of the sequence produced at the iterate \(k + 1\) and an extrapolation vector. The latter uses a parameter which can be calculated mathematically. We illustrate numerically this process by studying a free-boundary problems class.

Keywords: Accelerate process; Monotonous convergence; Method of successive approximations; Method of super/sub-solution

MSC 2010 No.: 49M25, 65B05, 65N22, 65N55

1. Introduction

This paper deals with the study of an iterative process for speeding up the successive approximations method:

\[ u^{k+1} = Tu^k + b, \quad k = 0, 1, \ldots, \]
where $T$ is a real $m \times m$ matrix and $b, u^k \in R^m$, in the case of monotonous convergence. This process has initially been proposed by Falcone (1984) & Miellou (1979) for solving a linear system and has been extended afterward by El-Tarazi (1986) for a nonlinear system. It consists in interrupting the iterations of the sequence $(u^k)$, $k = 1, 2, \ldots$, produced by the iterative method at the $k^{th}$ step and substituting $u^k$ by $\tilde{u}^k$, where $\tilde{u}^k$ is obtained by combining the vector $u^{k+1}$ and the extrapolation vector $u^k + \eta^k(u^k - u^{k-1})$,

with $\eta^k$ a real parameter to be calculated. We restart the iterative process with $\tilde{u}^k$ as an initial guess; this sequence $\tilde{u}^k$ is a better approximation to the solution that the iterations $u^{k+1}$ and $u^k$, and moreover, it preserves the monotony properties. In Laouar (1988) and Laouar and Abdelli (2005), it has been applied to solve a discrete quasi-variational inequality system. A hybrid acceleration procedure for nonlinear problems, similar to that described above, was developed by Brezinski and Cheheb (1998). Our primary goal, here, is to improve this process for a large system. For this, we illustrate this process by applying it to a class of free boundary problems (see Bensoussan and Lions (1978), Boulbrachene (1998), Chau, et al. (2017), Zhou (2007)).

We look for a function $u$ satisfying

$$\begin{cases}
a(u, u - v) \geq (f, v - u)_{L^2(\Omega)}, \\
u \leq M(u), v \leq M(u),
\end{cases}$$  \hspace{1cm} (1)$$

where $a(\cdot, \cdot)$ is a bilinear form, $(\cdot, \cdot)$ being the inner product in $L^2(\Omega)$, $f$ a regular given function in $L^2(\Omega)$. $M(u)$ represents the obstacles which are very important in the study of the quasi-variational inequality system (the impulsion control problems).

The outline of this paper is as follows. Section 2 describes the accelerative process and gives the algorithms. Section 3 presents a free boundary problem and analogous discrete problem. Last section gives the illustration of the accelerate process by considering two examples.

2. An Accelerate Process

2.1. Preliminaries and theory

In this section we introduce some useful materiel which we used in the sequel.

On $R^m$, the real $m$–dimensional linear space of column vector $u = (u_1, \ldots, u_m)^T$.

We consider the natural partial ordering defined by

for $u, v \in R^m$, $u < v \iff u_i < v_i, \ i = 1, \ldots, m$, 

for $u, v \in R^m$, $u \leq v \iff u_i \leq v_i, \ i = 1, \ldots, m$.

On $L(R^m)$ the linear space of real $m \times m$ matrices, we may consider a partial ordering analogous as follows

for $A, C \in L(R^m)$, $A < C \iff a_{i,j} < c_{i,j}, \ i, j = 1, \ldots, m$, 

for $A, C \in L(R^m)$, $A \leq C \iff a_{i,j} \leq c_{i,j}, \ i, j = 1, \ldots, m$. 
Let \( T \in L(R^m) \) and \( b \in R^m \), and consider the linear system
\[
    u = Tu + b,
\]
(2)
and the method of successive approximations
\[
    \left\{
        \begin{array}{l}
            \text{For any initial vector } u^0 \in R^m/ \\
            u^{k+1} = Tu^k + b, \quad k = 0, 1, 2, \ldots,
        \end{array}
    \right.
\]
(3)
denoting by \( u^* \) the fixed point of Equation (2).

It is known that if \( \rho(T) < 1 \) (\( \rho(T) \) is the spectral radius of \( T \)) then, the iterative method (3) converges to the solution \( u^* \) for any \( u^0 \in R^m \); of course, the convergence is not necessarily monotone (see Laouar and Abdelli (2005)).

**Definition 2.1.**

In (2), for any \( z \in R^m \), we say that

- a sub-solution if \( z \leq Tz + b \),
- a super-solution if \( Tz + b \leq z \).

**Remark.**

Note that if the spectral radius \( \rho(T) \) is less than unity, then the iteration (3) converges to the solution \( u^* \) of (2) for any \( u^0 \in R^m \). Furthermore, it is classically known (see Ortega and Rheinboldt (1970) for more general cases) that if
\[
    T \geq 0, \quad \rho(T) < 1 \quad \text{and} \quad Tu^0 + b \leq u^0 \quad \text{(resp. } u^0 \leq Tu^0 + b),
\]
then the sequence (3) is decreasing (resp. increasing) in partially ordered space \( R^m \) and converges to \( u^* \). Whereas when \( \rho(T) \) is close to unity, the convergence of (3) may be very slow.

Consider the following hypothesis
\[
    (H) \quad \left\{
        \begin{array}{l}
            T \in L(R^m) \text{ with } T \geq 0, \\
            \text{and } \rho(T) \text{ is strictly lower than } 1.
        \end{array}
    \right.
\]

**Lemma 2.3.**

Under the hypothesis \( (H) \) and for any \( u, v \in R^m \), \( Tu + b \leq u \) and \( Tv + b \leq v \). Let \( z \in R^m \) be defined by \( z = \min(u, v) \) [i.e. \( z_i = \min(u_i, v_i), \ i = 1, \ldots, m \)]. Then, we have
\[
    Tz + b \leq z.
\]

**Proof:**

By definition of \( z \), \( z_i = u_i \) (or \( z_i = v_i \)) for \( i = 1, \ldots, m \). Since, \( z \leq u \) (resp. \( z \leq v \)) and \( t_{i,j} \geq 0 \) (\( t_{i,j} \) the coefficients of the matrix \( T \)) then, for \( j = 1, \ldots, m \), we have
Then, for \( i = 1, \ldots, m \), we have

\[
(Tz + b - z)_{i} \leq (Tu + b - u)_{i} \leq 0 \quad (\text{resp.} \quad (Tv + b - v)_{i} \leq 0).
\]

Hence, we deduce that \( Tz + b \leq z \). \( \blacksquare \)

**Proposition 2.4.**

We suppose that the hypothesis \((H)\) is verified. Let \( Tu^{0} + b \leq u^{0} \) (resp. \( v^{0} \leq Tv^{0} + b \)), then the sequence \( u^{k} \) (resp. \( v^{k} \)) defined by

\[
\begin{align*}
    u^{k+1} &= Tu^{k} + b \quad (\text{resp.} \quad v^{k+1} = Tv^{k} + b), \\
    u^{*} &\leq \ldots \leq u^{k+1} \leq u^{k} \leq \ldots \leq u^{0} \quad \text{and} \quad \lim_{k \to \infty} u^{k} = u^{*} \quad (\text{resp.} \quad v^{0} \leq \ldots \leq v^{k} \leq v^{k+1} \leq \ldots \leq v^{*} \quad \text{and} \quad \lim_{k \to \infty} v^{k} = v^{*}).
\end{align*}
\]

**Proof:**

We have \( \rho(T) < 1 \) and \( T \geq 0 \), then \( (I - T)^{-1} \geq 0 \). So, \( (I - T) \) is M-matrix with \( Tu^{0} + b \leq u^{0} \) (resp. \( v^{0} \leq Tv^{0} + b \)), we can prove easily this proposition. \( \blacksquare \)

**Theorem 2.5.**

Let the hypothesis \((H)\) be verified. Let \( Tu^{0} + b \leq u^{0} \) and a parameter \( \eta^{k} \) (\( \eta^{k} > 0 \)) defined by

\[
\eta^{k} = \min_{i \in m} \left\{ \frac{[T(u^{k-1} - u^{k})]_{i}}{[(I - T)(u^{k-1} - u^{k})]_{i}} \right\} = \min_{i \in m} \left\{ \frac{[(I - T)u^{k} - b]_{i}}{[(I - T)(u^{k-1} - u^{k})]_{i}} \right\},
\]

where the minimum is taken over all \( i \) for which

\[
[(I - T)(u^{k-1} - u^{k})]_{i} > 0 \quad \text{and} \quad u^{k+1} = Tu^{k} + b, \quad \text{for} \quad k = 1, 2, \ldots
\]

Then

\[
\tilde{u}^{k} = u^{k} + \eta^{k}(u^{k} - u^{k-1}),
\]

satisfies

\[
u^{*} \leq \tilde{u}^{k} \leq u^{k+1} \leq u^{k} \quad \text{and} \quad Tu^{k} + b \leq \tilde{u}^{k}.
\]
**Proof:**

Under the hypothesis (H), \( u^k \) satisfies Proposition 2.4 and \( u^{k-1} \leq u^k \) for all \( k \). If \( u^{k-1} = u^k \), then \( u^k = u^* \) and the proof is obvious.

Now, we suppose that \( u^{k-1} \neq u^k \). As \( (I - T)^{-1} \geq 0 \), it follows that \((I - T)(u^{k-1} - u^k)\) has at least one positive component. Thus, the parameter \( \eta^k \) is well defined and positive.

From (4), we have

\[
\eta^k \left[ (I - T)(u^k - u^{k-1}) \right]_i \leq \left[ (I - T)u^k - b \right]_i , \text{ for } i = 1, ..., n,
\]

which is true even if

\[
\left[ (I - T)(u^{k-1} - u^k) \right]_i \leq 0, \text{ since } (I - T)u^k - b \geq 0.
\]

Hence,

\[
T \left[ u^k + \eta^k(u^k - u^{k-1}) \right] + b \leq u^k + \eta^k(u^k - u^{k-1}), \text{ with } Tu^{k+1} + b \leq u^{k+1}.
\]

By using Lemma 2.3, we have

\[
Tv^k + b \leq \bar{v}^k, \quad \bar{u}^{k+1} \leq u^{k+1} \leq u^k
\]

and

\[
(I - T)u^* - b \leq (I - T)\bar{u}^k - b, \quad \text{with } (I - T) \geq 0.
\]

Hence, \( u^* \leq \bar{u}^k \). So, the proof of Theorem 2.5 is completed.

**Theorem 2.6.**

Let the hypothesis (H) be verified. Let \( v^0 \leq Tv^0 + b \) and a parameter \( \theta^k (\theta^k > 0) \) defined by

\[
\theta^k = \min_{i \in m} \left\{ \left[ \frac{T(v^{k-1} - v^k)\}_{i}}{(I - T)(v^{k-1} - v^k)\}_{i}} \right\} = \min_{i \in m} \left\{ \left[ \frac{(I - T)v^k - b\}_{i}}{(I - T)(v^{k-1} - v^k)\}_{i}} \right\}, \quad (5)
\]

where the minimum is taken over all \( i \) for which

\[
\left[ (I - T)(v^{k-1} - v^k) \right]_i < 0 \text{ and } v^{k+1} = Tv^k + b, \quad k = 1, 2, ...
\]

Then

\[
\bar{v}^k = v^k + \theta^k(v^k - v^{k-1}),
\]

satisfies

\[
v^k \leq v^{k+1} \leq \bar{v}^k \leq u^* \quad \text{and} \quad \bar{v}^k \leq T\bar{v}^k + b.
\]

**Proof:**

In a similar way of Theorem 2.5, we can easily show Theorem 2.6.
Of course under the assumption \((H)\) of the above Theorems 2.5 and 2.6, we can guarantee two sided error estimate
\[ v^k \leq \tilde{v}^k \leq u^* \leq \tilde{u}^k \leq u^k, \]
which allows us to obtain an approximation to the exact solution \(u^*\) to any desired tolerance.

### 2.2. Original and accelerated algorithms

Denoting by \(Alg_1\) the original algorithm and \(Alg_2\) the accelerated algorithm, we now give a description of the \(Alg_1\) and \(Alg_2\), respectively.

**Algorithm Alg_1:**

**Step 0:** Consider the initial guess \(u^0, v^0 \in \mathbb{R}^m\) such that
\[ u^0 \leq Tu^0 + b \quad \text{and} \quad Tv^0 + b \leq v^0. \]

**Step 1:** For \(k = 0, 1, \ldots\)
\[
\begin{cases}
  v^{k+1} = Tu^k + b, \\
  v^{k+1} = Tv^k + b.
\end{cases}
\]

**Algorithm Alg_2:**

**Step 0:** Consider the initial guess \(u^0, v^0 \in \mathbb{R}^m\) such that
\[ u^0 \leq Tu^0 + b \quad \text{and} \quad Tv^0 + b \leq v^0. \]

**Step 1:** For \(k = 1, 2, \ldots\)
\[
\begin{cases}
  u^{k+1} = \max [Tu^k + b, u^k + \eta^k (u^k - u^{k-1})], \\
  v^{k+1} = \min [Tv^k + b, v^k + \theta^k (v^k - v^{k-1})],
\end{cases}
\]
where the parameter \(\eta^k\) (resp. \(\theta^k\)) is calculated by the expression (4) (resp. by (5)).

To solve the iterative systems (6) and (7), we use the Jacobi method \([I - T] = A\), where \(A = a_{i,j}, \quad 1 \leq i, j \leq m\); we denote by \(D = (d_{i,j})_{1 \leq i,j \leq m}\) a diagonal matrix, where \(d_{i,j} = a_{i,j}\), if \(i = j\) and \(d_{i,j} = 0\) if \(i \neq j\), \(-E (-F)\) is strictly lower (resp. upper) triangular matrix of the \(A\).

Thus, the algorithm is written as
\[
\begin{cases}
  \text{For any } u^0 \in \mathbb{R}^m \text{ arbitrary data}, \\
  u^{k+1} = (I_n - D^{-1}(E + F))u^k + D^{-1}b, \quad k = 0, 1, \ldots
\end{cases}
\]

For the convergence test of the algorithm, we use the norm \(\| u^k - v^k \|_{\infty} < \varepsilon\), where \(\varepsilon\) is a tolerance. The initialization process of vectors \(u^0\) and \(v^0\) is defined by
\[
(I - T)u^0 < b \quad \text{(resp. } b < (I - T)v^0).\]
Step 0: We can choose the initial vectors $u^0$ and $v^0$ as follows.

$$u^0 = -v^0 = - (\delta, ..., \delta)^t, \quad \text{where} \quad \delta > \max \left( \frac{\bar{b}}{\lambda}, \frac{-b}{\lambda} \right) > 0,$$

with

$$\lambda = \min_i \left( \sum_j a_{i,j} \right) > 0, \quad b = \min_i (b_i) \quad \text{and} \quad \bar{b} = \max_i (b_i).$$

3. Class of free boundary problems

In order to present the study at least for a large class of the problems, we take an economic problem from the general examples (we refer to the book of Bensoussan and Lions(1978)). Our objective, here, is limited to give numerical examples for illustrating the accelerative process, so we do not intend to present the complete study of this problem (for more details, see Bensoussan and Lions (1978) and Boulbrachene (1998)).

Indeed, we want to solve a class of the following general problem. Let $\Omega$ be a bounded domain of $\mathbb{R}^m$, with regular boundary $\partial \Omega$.

\begin{equation}
\begin{aligned}
(P) \quad & \text{Find } u \text{ such that } \\
& a(u, u - v) \geq (f, v - u)_{L^2(\Omega)}, \\
& u \leq M(u), \quad v \leq M(u),
\end{aligned}
\end{equation}

where

$$a(u, v) = \sum_{i,j=1}^{n} \int_{\Omega} \sigma_{i,j}(x) \frac{\partial u}{\partial x_i} \frac{\partial v}{\partial x_j} dx + \sum_{j=1}^{n} \int_{\Omega} \mu_j(x) \frac{\partial u}{\partial x_j} v dx + \int_{\Omega} \alpha_0(x) uv dx,$$

the coefficients $\sigma_{i,j}$, $\mu_j$ and $\alpha_0 \in L^\infty(\Omega)$, for $i, j = 1, ..., n$, with $\alpha_0 \geq 0$, $(..)$ being the inner product in $L^2(\Omega)$ and $f$ a regular given function in $L^2(\Omega)$. $M(u)$ represents the obstacles which are very important in the study of the quasi-variational inequalities which invert as impulsion control problems.

The general problem $(P)$ is theoretically well understood from mathematical and analytic point of view (see Bensoussan and Lions (1978)) and can be written explicitly under other form of three sub-problems as follows.

For $i = 1, 3$, find $u_i \in \mathbb{R}^m$ such that

\begin{equation}
\begin{aligned}
\{ & A_i u_i \leq f_i, \\
& u_i \leq M(u_i), \\
& (A_i u_i - f_i)^t M(u_i) = 0, \}
\end{aligned}
\end{equation}

where $A_1$, $A_2$ and $A_3$ are three operators which will define in the sequel. $M(u)$ is define by

$$M(u_i) = \inf_{i,j} \{ \Psi_{i,j} + u_i \},$$
where $\Psi_{i,j}$ is the obstacles for $i \neq j$ and $i, j \in \{1, 2, 3\}$.

The economic problem means to adjust the period-time in which a regime is used in order to satisfy the demand at the lowest cost (see Bensoussan and Lions (1978)).

Other formulation of the problem (11) is given by

For $i = 1, 3$, find $u_i \in \mathbb{R}^m$ such that

$$\max \left[ (A_i u_i - f_i)^t (u_i - \inf_{i,j} (\Psi_{i,j} + u_i)) \right] = 0. \quad (12)$$

The problems (11) are presented more explicitly as follows. Find the respective solutions $u_1, u_2, u_3$ of the three sub-problems such that

$$\begin{align*}
(P_1) & \quad A_1 u_1 \leq f_1, \\
& \quad u_1 \leq \inf (\Psi_{1,2} + u_2, \Psi_{1,3} + u_3), \\
& \quad (A_1 u_1 - f_1)^t (u_1 - \inf (\Psi_{1,2} + u_2, \Psi_{1,3} + u_3)) = 0, \\
& \quad A_2 u_2 \leq f_2, \\
(P_2) & \quad u_2 \leq \inf (\Psi_{2,1} + u_1, \Psi_{2,3} + u_3), \\
& \quad (A_2 u_2 - f_2)^t (u_2 - \inf (\Psi_{2,1} + u_1, \Psi_{2,3} + u_3)) = 0, \\
& \quad A_3 u_3 \leq f_3, \\
(P_3) & \quad u_3 \leq \inf (\Psi_{3,1} + u_1, \Psi_{3,2} + u_2), \\
& \quad (A_3 u_3 - f_3)^t (u_3 - \inf (\Psi_{3,1} + u_1, \Psi_{3,2} + u_2)) = 0,
\end{align*}$$

(13)

with boundaries conditions $u_1 = u_2 = u_3 = 0$ and $f_1, f_2$ and $f_3$ given positive functions. For $i \neq j$ and $i, j \in \{1, 2, 3\}$, $\Psi_{i,j}$ is the fixed cost and represents the obstacles (see Bensoussan and Lions (1978)).

**Remark.**

The procedure of passing from one regime to the other is easily described from $(Ps)$; for example, one pays $\Psi_{1,2}$ and $\Psi_{1,3}$ when we pass from the regime $(P_1)$ to the regime $(P_2)$, but if

$$u_1 \leq \inf (\Psi_{1,2} + u_2, \Psi_{1,3} + u_3),$$

is not verified, then one projects.

Similarly, one pays $\Psi_{3,1}$ and $\Psi_{3,2}$ when we pass from the regime $(P_2)$ to the regime $(P_3)$, but if

$$u_2 \leq \inf (\Psi_{2,1} + u_1, \Psi_{2,3} + u_3),$$

is not verified, then we project (for more details, we refer to the book of Bensoussan and Lions (1978)).

The operators $A_1, A_2$ and $A_3$ are given by
\[ \begin{align*}
A_1 u_1 &= - \sum_{i=1}^{n} \sigma_{i,j}(x) \frac{\partial^2 u_1}{\partial x_i^2} + \sum_{j=1}^{n} \mu_i(x) \frac{\partial u_1}{\partial x_i} + \alpha_0(x) u_1, \\
A_2 u_2 &= - \sum_{i=1}^{n} \sigma_{i,j}(x) \frac{\partial^2 u_2}{\partial x_i^2} + \alpha_0(x) u_2, \\
A_3 u_3 &= - \sum_{i=1}^{n} \sigma_{i,j}(x) \frac{\partial^2 u_3}{\partial x_i^2}.
\end{align*} \tag{14} \]

Note that the coefficients \( \sigma_{i,j}(x), \mu_i(x) \) and \( \alpha_0(x) \) are given regular functions which are taken as constant in numerical experiment.

### 3.1. Analogous discrete problem

The discrete version of the problem \((P)\) can be written as

\[ (P_h) \quad \begin{align*}
\text{Find } u_h \text{ a discrete solution such that } \\
a_h(u_h, v_h - u_h) &\geq (f_h, v_h - u_h), \\
u_h &\leq r_h M_h, \quad v_h \leq r_h M_h,
\end{align*} \tag{15} \]

where \( r_h \) is an usual interpolation operator.

The fixed-point application associated to the problem \((P_h)\) is defined by

\[ (T_h) \quad \begin{align*}
T_h : (L^\infty(\Omega_h))^+ &\to V_h, \\
w &\mapsto T_h w = z_h(w),
\end{align*} \tag{16} \]

where \( V_h \) is a \( P_1 \) finite element space approximating \( H^1(\Omega_h) \) and \( z_h(w) \) the discrete solution of the following problem:

\[ (P'_h) \quad \begin{align*}
a_h(z_h(w), v_h - z_h(w)) &\geq (f_h, v_h - z_h(w)), \\
z_h(w) &\leq r_h M_h(w), \quad v_h \leq r_h M_h.
\end{align*} \tag{17} \]

### 4. Numerical examples

For illustrating the considered accelerate process, we give two numerical examples and evaluate the execution time of solution by using the following formula

\[ q = \frac{\text{execution time of the algorithm Alg2}}{\text{execution time of the algorithm Alg1}}. \]

**Example 4.1.**

The first example treats the particular case of the problem \((14 - I)\) by taking \( M(u) = \Psi \). For this we discretize the problem \((P_h)\) by taking \( \Omega = [0,1] \times [0,1] \) and choosing a regular mesh of pace \( h \) \((h = 1/(m + 1), m > 0)\). We use a standard discretization by the five point-usual finite difference scheme and obtain the following system:

\[ A_h u_h = F_h, \tag{18} \]
where \( A_h \) is the matrix of discretization, \( u_h \) a solution vector and \( F_h = (h^2 f_1, ..., h^2 f_m)^T \).

Taking

\[
\begin{align*}
  k_1 &= 4 \left( \frac{\sigma_1^2}{2} + \frac{\sigma_2^2}{2} \right) + \alpha_0 h^2, \\
  k_2 &= -\frac{\sigma_1^2}{2} + \frac{\mu_1 h}{2}, \\
  k_3 &= -\frac{\sigma_1^2}{2} - \frac{\mu_1 h}{2}, \\
  k_4 &= -\frac{\sigma_2^2}{2} + \frac{\mu_2 h}{2}, \\
  k_5 &= \frac{\sigma_2^2}{2} - \frac{\mu_2 h}{2},
\end{align*}
\]

where \( \sigma_1 = \sigma_2 \approx \sigma_{i,j}(x) \) and \( \mu_1 = \mu_2 = \mu_j \), for \( i, j = 1, ..., m \).

The coefficients of the matrix are given by

\[
\begin{align*}
  a_{i,i} &= k_1 \quad \text{for} \quad i = 1, m, \\
  a_{i,i+1} &= \begin{cases} k_2 & \text{if} \quad i = 1, m \quad \text{and} \quad i \neq n, 2n, ..., m - 1, \\
  0 & \text{if} \quad i = n, 2n, ..., m - 1, \\
  a_{i,i-1} &= \begin{cases} k_3 & \text{if} \quad i = 2, m \quad \text{and} \quad i \neq n, 2n, ..., m - 1, \\
  0 & \text{if} \quad i = n, 2n, ..., m - 1, \\
  a_{i,i+n} &= k_4 \quad \text{and} \quad a_{i+n,i} = k_5 \quad \text{for} \quad i = 1, ..., m - 1.
\end{cases}
\end{align*}
\]

We note that the matrix \( A_h \) has a multi-diagonal structure and does not symmetric. To solve the system \((18)\), we use the Jacobi method and project on convex space (i.e., if the iteration \( u^k \leq r_h \Psi_h \) and \( v^k \leq r_h \Psi_h \), otherwise, we take the iteration \( u^k \) and \( v^k \) equal to the obstacle, respectively). Thus, we calculate the super-solution and sub-solution. Therefore we are evaluated the cpu execution time in one percent of a second of the original Algorithm Alg1 before the acceleration and the execution time of the accelerated Algorithm Alg2.

To simulate, we take the following data \( \sigma_1 = \sigma_2 = \sqrt{2}, \alpha_0 = 100, \mu_1 = \mu_2 = 0.01, \Psi \) a positive constant and tolerance \( \varepsilon = 10^{-14} \).

We present some results in the following tables.

**Table 1.** The execution time of the Algorithm Alg1.

<table>
<thead>
<tr>
<th>( m )</th>
<th>Iterations</th>
<th>Time cpu (one percent of a second)</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
<td>65</td>
<td>36.8000</td>
</tr>
<tr>
<td>169</td>
<td>141</td>
<td>414.960</td>
</tr>
<tr>
<td>225</td>
<td>180</td>
<td>896.440</td>
</tr>
<tr>
<td>289</td>
<td>202</td>
<td>1272.020</td>
</tr>
</tbody>
</table>

**Table 2.** The execution time of the Algorithm Alg2.

<table>
<thead>
<tr>
<th>( m )</th>
<th>Iterations</th>
<th>Time cpu (one percent of a second)</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
<td>30</td>
<td>26.5600</td>
</tr>
<tr>
<td>169</td>
<td>69</td>
<td>256.560</td>
</tr>
<tr>
<td>225</td>
<td>88</td>
<td>340.760</td>
</tr>
<tr>
<td>289</td>
<td>93</td>
<td>658.670</td>
</tr>
</tbody>
</table>
Note that the iterations number cannot be considered here, as a criterion of comparison because the Algorithm $\text{Alg}_2$ is different of the Algorithm $\text{Alg}_1$.

Now, we represent graphically the above result of the tables (see Figure 1).

![Figure 1](image)

We remark that the situation, here, is a more favorable that in El-Tarazi (1986) and Laouar and Abdelli (2005), since the result obtained in Tables 1 and 2, shows that there is a better acceleration of convergence (for example $m = 64$, we gain approximately 30% cpu time). We notice that when $m$ increases, the gain in time can reach up to 50%.

**Example 4.2.**

In the second example, we consider the general problem (13) in three dimensional (i.e., $\Omega = [0,1] \times [0,1] \times [0,1]$). For the discretization of the problems (14, $I$), (14, $II$) and (14, $III$), we use a standard discretization (the nine point-usual finite difference scheme). Thus, we obtain the corresponding systems, respectively.

\[
\begin{align*}
A_h^{(1)} u_h &= F_h^{(1)}, \\
A_h^{(2)} v_h &= F_h^{(2)}, \\
A_h^{(3)} w_h &= F_h^{(3)},
\end{align*}
\]  

(21)

where $A_h^{(1)}$, $A_h^{(2)}$ and $A_h^{(3)}$ are the discretization matrices of the operators $A_1, A_2$ and $A_3$, respectively; $u_h$, $v_h$ and $w_h$ are the solutions vectors of $(I_h)$, $(II_h)$ and $(III_h)$; $F_h^{(1)}$, $F_h^{(2)}$ and $F_h^{(3)}$ are the second members.

We solve the systems (19, $I_h$), (19, $II_h$) and (19, $III_h$) by Gauss-Seidel method which is presented as follows.

For $i = \overline{1,m}$, we have

\[
\begin{align*}
\widetilde{u}_i^{(k+1)} &= - \sum_{i<j} a_{i,j} u_i^{(k)} - \sum_{i>j} a_{i,j} u_i^{(k+1)} + F_h^{(i)}, \\
\widetilde{w}_i^{(k+1)} &= \text{proj}_V \widetilde{u}_i^{(k+1)},
\end{align*}
\]  

(22)

\begin{flushright}
$k = 0,1,2,\ldots$
\end{flushright}
where

\[ V = \left\{ u_i^{(k+1)} / u_i^{(k+1)} \leq \inf (\Psi_{i,j} + v_i^{(k)}, \Psi_{i,j} + w_i^{(k)}) \right\}, \]

with \( v_i^{(k)}, w_i^{(k)} \) the calculated iterations for the systems (19, II\(_h\)) and (19, III\(_h\)), respectively.

For simulation, we have taken the obstacles \( \Psi_{1,2} = \Psi_{2,1} = 3, \Psi_{1,3} = \Psi_{3,1} = 4 \) and \( \Psi_{2,3} = \Psi_{3,2} = 2.5 \); the coefficients \( \sigma_{i,j} = 2, \mu_j = 1 \) and \( \alpha_0 = 4 \); the initial vectors \( u^{(0)} = v^{(0)} = w^{(0)} = 1, 7 \); the tolerance \( \varepsilon = 10^{-8} \).

We present some results in the following tables:

**Table 3.** The execution time of the Algorithm Alg1.

<table>
<thead>
<tr>
<th>h = 1/(m + 1)</th>
<th>Iterations</th>
<th>Time cpu (second)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/8</td>
<td>13</td>
<td>3.06</td>
</tr>
<tr>
<td>1/11</td>
<td>12</td>
<td>4.44</td>
</tr>
<tr>
<td>1/16</td>
<td>15</td>
<td>12.72</td>
</tr>
<tr>
<td>1/32</td>
<td>45</td>
<td>30.11</td>
</tr>
</tbody>
</table>

**Table 4.** The execution time of the Algorithm Alg2.

<table>
<thead>
<tr>
<th>h = 1/(m + 1)</th>
<th>Iterations</th>
<th>Time cpu (second)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/8</td>
<td>12</td>
<td>2.55</td>
</tr>
<tr>
<td>1/11</td>
<td>8</td>
<td>3.77</td>
</tr>
<tr>
<td>1/16</td>
<td>9</td>
<td>11.73</td>
</tr>
<tr>
<td>1/32</td>
<td>30</td>
<td>25.09</td>
</tr>
</tbody>
</table>

As we said previously the iterations number cannot be considered, here, as a criterion of comparison because the Algorithm Alg2 is not identical to the Algorithm Alg1.

### 5. Remarks and Conclusion

We remark that our result is a more favorable than in Laouar and Abdelli (2005) & El-Tarazi (1986), since the result obtained, in Tables 1 and 2, shows that there is a better acceleration of convergence (for example \( m = 64 \), we gain approximately 30% cpu time). We notice that when \( m \) increases, the gain in time can reach up to 50%. The results in Tables 3 and 4 show that there is an acceleration of convergence. One gains approximately 20% of the time with respect to the time of the original Algorithm Alg1. However the situation is a less favorable as in Example 1. The gain of time is approximately similar to the obtained results in El-Tarazi (1986) & Laouar and Abdelli (2005).

This study introduces a process of convergence acceleration as a numerical algorithm for a class of free boundary problems, where the problem of the obstacle is representative. We were only concerned with setting this acceleration process to test whether it is robust. Indeed, important theoretical questions concerning the sensitivity of this process to the optimal choices of the relaxation
parameter were not addressed in this study. This process can be extended to free parabolic boundary problems (the Stefan problem) and optimal control problems of elliptic type with constraints on state and/or control.
