ABSTRACT

The effect of viscous dissipation and heat absorption on a steady two-dimensional natural convection laminar flow of viscous incompressible fluid with uniform surface temperature along a vertical wavy surface has been investigated. Using the appropriate variables; the basic equations are transformed to convenient form and then solved numerically employing very efficient method, namely Keller-Box method (KBM). Numerical results are presented by the shearing stress in terms of the local skin-friction coefficient; the rate of heat transfer in terms of local Nusselt number, streamline and isotherms, respectively for a wide range of the viscous dissipation parameter $N$ and heat absorption parameter $Q$. Increasing $Q$ and lessening $N$ cause the enhancement of heat transfer rate.

KEYWORDS: Viscous dissipation; Heat absorption; Natural convection; Keller-Box method; Wavy surface.

MSC (2010) No.: 76D05, 76R10

1. INTRODUCTION

Many scientists investigated viscous dissipation for various purposes in science separately or in presence of heat generation or heat absorption. Gebhart (1962) studied the effects of viscous dissipation in natural convection and then in external natural convection flow
together with Mollendorf (1969). Natural convection was introduced along a vertical wavy surface by Yao (1983). Vajravelu and Hadjinolaou (1993) studied the heat transfer characteristics in the laminar boundary layer of a viscous fluid over a stretching sheet with viscous dissipation or frictional heating and internal heat generation. In this study they considered that the volumetric rate of heat generation, \( q'' \, [W/m^3] \), should be \( q'' = Q_0(T - T_\infty) \), for \( T \geq T_\infty \) and equal to zero for \( T < T_\infty \), where \( Q_0 \) is the heat generation/absorption constant. Hossain and Rees (1999) first investigated combined heat and mass transfer in natural convection flow from a vertical wavy surface and then Jang et al. (2003) investigated natural convection heat and mass transfer along a vertical wavy surface. Molla et al. (2004) studied natural convection flow along a vertical wavy surface with uniform surface temperature in presence of heat generation/absorption.

From the above one thing is clear that yet it has not been justified the effects of viscous dissipation and heat absorption together on natural convection flow along a vertical wavy surface. The object of the study is to show the effect of our present work.

2. FORMULATION OF THE PROBLEM

The boundary layer analysis outlined below allows \( \bar{\sigma}(X) \) being arbitrary, but our detailed numerical work assumed that the surface exhibits sinusoidal deformations. The wavy surface may be described by

\[
Y_w = \bar{\sigma}(X) = \alpha \sin\left(\frac{n \pi X}{L}\right),
\]

where \( L \) is the wavelength associated with the wavy surface.

The geometry of the wavy surface and the two-dimensional Cartesian coordinate system are shown in Figure 1.
The conservation equations for the flow characterized with steady, laminar and two-dimensional boundary layer; under the usual Boussinesq approximation, dimensionless form of the continuity, momentum and energy equations can be written as:

\[
\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0, \tag{2}
\]

\[
u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = -\frac{1}{\rho} \frac{\partial p}{\partial x} + Gr^{1/4} \sigma_x \frac{\partial p}{\partial y} + \left(1 + \sigma_x^2\right) \frac{\partial^2 u}{\partial y^2} + \theta, \tag{3}
\]

\[
\sigma_x \left( \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right) = -Gr^{1/4} \frac{\partial p}{\partial y} + \sigma_x \left(1 + \sigma_x^2\right) \frac{\partial^2 u}{\partial y^2} - \sigma_x u^2, \tag{4}
\]

\[
u \frac{\partial \theta}{\partial x} + v \frac{\partial \theta}{\partial y} = \frac{1}{Pr} \left(1 + \sigma_x^2\right) \frac{\partial^2 \theta}{\partial y^2} + Q \theta + N \left( \frac{\partial u}{\partial y} \right)^2, \tag{5}
\]

where \( Pr = \frac{C_p \mu}{k} \) is the Prandtl number, \( Q = \frac{Q_0 L^2}{\mu C_p G r^{1/2}} \) is the heat absorption parameter and \( N = \frac{\nu^2 G r}{L^2 C_p (T_w - T_\infty)} \) is the viscous dissipation parameter.

The following dimensionless variables are introduced for non-dimensionalizing the governing equations,

\[
x = \frac{X}{L}, \quad y = \frac{Y - \bar{\sigma}}{L} Gr^{1/4}, \quad \rho = \frac{L^2}{\rho \nu^2} Gr^{-1} \rho, \quad \theta = \frac{T - T_\infty}{T_w - T_\infty}, \quad \sigma_x = \frac{d \sigma}{d X}, \quad \frac{G r}{\nu^2} = L^3.
\]
where θ is the non-dimensional temperature function and \((u, v)\) are the dimensionless velocity components.

It can easily be seen that the convection induced by the wavy surface is described by equations (2)–(5). We further notice that, equation (5) indicates that the pressure gradient along the y-direction is \(O(Gr^{-1/4})\), which implies that lowest order pressure gradient along x-direction can be determined from the inviscid flow solution. For the present problem this pressure gradient \((\partial p / \partial x = 0)\) is zero. Equation (4) further shows that \(Gr^{1/4} \partial p / \partial y\) is \(O(1)\) and is determined by the left-hand side of this equation. Thus, the elimination of \(\partial p / \partial y\) from equations (3) and (4) leads to

\[
u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = (1 + \sigma_x^2) \frac{\partial^2 u}{\partial y^2} - \frac{\sigma_y \sigma_{xx}}{1 + \sigma_x^2} u^2 + \frac{1}{1 + \sigma_x^2} \theta. \tag{6}
\]

The corresponding boundary conditions for the present problem are:

\[
\begin{align*}
  u &= v = 0, \quad \theta = 1, \quad \text{at} \quad y = 0, \\
  u &= \theta = 0, \quad p = 0, \quad \text{as} \quad y \to \infty.
\end{align*} \tag{7}
\]

Now we introduce the following transformations to reduce the governing equations to a convenient form:

\[
\psi = x^{3/4} f(x, \eta), \quad \eta = y x^{-1/4}, \quad \theta = \theta(x, \eta). \tag{8}
\]

Introducing the transformations given in Equation (8) and into Equation (6) and (5), the following system of nonlinear equations are obtained

\[
(1 + \sigma_x^2) f''' + \frac{3}{4} f''' - \left(1 + \frac{x \sigma \sigma_{xx}}{1 + \sigma_x^2}\right) f'^2 + \frac{1}{1 + \sigma_x^2} \theta = x \left(f'\frac{\partial f}{\partial x} - f''\frac{\partial f}{\partial x}\right). \tag{9}
\]

\[
\frac{1}{Pr} \left(1 + \sigma_x^2\right) \theta'' + \frac{3}{4} f' \theta' + x^{1/2} Q \theta + Nxf''^2 = x \left(f'\frac{\partial \theta}{\partial x} - \theta'\frac{\partial f}{\partial x}\right). \tag{10}
\]

The boundary conditions (7) now take the following form:
\[ f(x,\sigma) = f'(x,\sigma) = 0, \quad \theta(x,\sigma) = 1, \]
\[ f'(x,\infty) = 0, \quad \theta(x,\infty) = 0. \]  \hspace{1cm} (11)

The local skin friction coefficient \( C_{fx} \) and the rate of heat transfer in terms of the local Nusselt number \( Nu_x \) takes the following form:

\[ C_{fx} \left( Gr / x \right)^{1 / 4} / 2 = \sqrt{1 + \sigma_x^2} f^*(x,\sigma), \]  \hspace{1cm} (12)

\[ Nu_x \left( Gr / x \right)^{-1 / 4} = -\sqrt{1 + \sigma_x^2} \theta'(x,\sigma). \]  \hspace{1cm} (13)

3. METHOD OF SOLUTION

The governing equations are solved numerically with the help of implicit finite difference method together with the Keller-Box scheme (1974). The discretization of momentum and energy equations are carried out with respect to non-dimensional coordinates \( x \) and \( \eta \) to convey the equations in finite difference form by approximating the functions and their derivatives in terms of central differences in both the coordinate directions. Then the required equations are to be linearized by using the Newton’s Quasi-linearization method. The linear algebraic equations can be written in a block matrix which forms a coefficient matrix. The whole procedure namely reduction to first order followed by central difference approximations, Newton’s Quasi-linearization method and the block Thomas algorithm, is well known as Keller-box method.

4. RESULTS AND DISCUSSION

Here we have shown the combined effects of viscous dissipation and heat absorption on natural convection flow of viscous incompressible fluid along a vertical wavy surface. The skin friction coefficient \( C_{fx} \), the rate of heat transfer in terms of Nusselt number \( Nu_x \), the streamlines as well as the isotherms are shown graphically in Figures 2 to 5 for different values of the heat absorption parameter \( Q \) and the viscous dissipation parameter \( N \).

From the Figures 2(a) and (b), it is noted that the higher value of \( N \) accelerates the fluid flow and increases the temperature so with the increasing of viscous dissipation parameter \( N = (0.0, 0.4, 1.0, 1.5, 2.0) \), the skin friction coefficient \( C_{fx} \) increases along the upstream direction of the surface and the heat transfer rates in terms of the local Nusselt number \( Nu_x \) decreases.
Figure 2. Effect of $N$ on (a) skin friction coefficient $C_{fx}$ and (b) rate of heat transfer $Nu_x$ while $\alpha = 0.3$ and $Pr = 1.73$

From Figures 3(a) and (b), it is observed that the heat absorption mechanism does not create a layer of hot fluid near the surface so the temperature of the fluid decreases the surface temperature and temperature gradient increases. Thus the values of heat absorption parameter $Q = (0.0, -0.2, -0.5, -0.8)$ leads to decrease the local skin friction coefficient $C_{fx}$ and increase the local rate of heat transfer $Nu_x$ at different position of $x$.

Figure 3. Effect of $Q$ on (a) skin friction coefficient $C_{fx}$ and (b) rate of heat transfer $Nu_x$ while $\alpha = 0.3$ and $Pr = 1.73$

Figures 4 and 5 show the with and without effect of viscous dissipation parameter $N$ and heat absorption parameter $Q$ together on the formulation of streamlines and isotherms respectively while $Pr = 1.73$ and $\alpha = 0.3$. It is noted that with the effect of $N$, the velocity boundary layer becomes thicker and when $Q$ increases the opposite results observed. The thermal boundary layer becomes thicker gradually for the effect of $N$. The temperature distribution decreases in presence of heat absorption parameter $Q$. The maximum value of $\psi_{max}$ is 23.86 for $N = 2.0$. 
5. CONCLUSION

The effects of the heat absorption parameter $Q$ and the viscous dissipation parameter $N$ on natural convection flow of viscous incompressible fluid along a vertical wavy surface have been investigated. From the present investigation the following conclusions may be drawn:

**Figure 4.** Streamlines for (a) $N = 0.0, Q = 0.0$ (b) $N = 2.0, Q = 0.0$ (c) $N = 0.0, Q = -0.8$ and (d) $N = 2.0, Q = -0.8$ while $Pr = 1.73$ and $\alpha = 0.3$

**Figure 5.** Isotherms for (a) $N = 0.0, Q = 0.0$ (b) $N = 2.0, Q = 0.0$ (c) $N = 0.0, Q = -0.8$ and (d) $N = 2.0, Q = -0.8$ while $Pr = 1.73$ and $\alpha = 0.3$
The skin friction coefficient $C_{fx}$ has increased and the rate of heat transfer in terms of Nusselt number $Nu_x$ has decreased for increasing values of $N$ and opposite results have happened for heat absorption parameter $Q$.

Streamlines have changed slightly too upper and the same results are observed for thermal boundary layer thickness with the increasing values of viscous dissipation parameter $N$ and opposite results have observed for heat absorption parameter $Q$.
